Mapping forest structure along the southern Blue Ridge Parkway from LiDAR

Steven P Norman (US Forest Service)
Jitendra Kumar (Oak Ridge National Lab.)
William W Hargrove (US Forest Service)
Forrest Hoffman (Oak Ridge National Lab.)
Douglas Newcomb (US Fish and Wildlife Service)

Blue Ridge Parkway Research and Science Symposium Folk Arts Center, Asheville, NC April 12, 2016

Focus

(1) Motivating questions:

- How different is the BRP from surrounding lands?
- Can we see *edge effects* to structure that are important for management?

(2) The dataset:

2005-06 North Carolina LiDAR for western NC including 13 counties; roughly 14.5 million 60 foot grid cells (~1,800 mi²)

(3) LiDAR products used in analysis:

- Maximum vegetation height
- A full above-ground structural classification involving ~479 million gridded 5' height band values and billions of LiDAR returns

NC Airborne LiDAR dataset and processing

Phase III data collected for flood hazard mapping (leaf off, 2005-2006). Use of above ground aspects (veg.), an after thought.

Max canopy height at 60' grid resolution was calculated from a highresolution LiDAR DEM from same effort.

Classification of vertical structures:

- (1) Point height calculated from high res DEM
- (2) Extreme values removed
- (3) Density calculated across 5 ft. height bands
- (4) Relative density calculated as % of above ground points in each band

BROAD

PHASE III

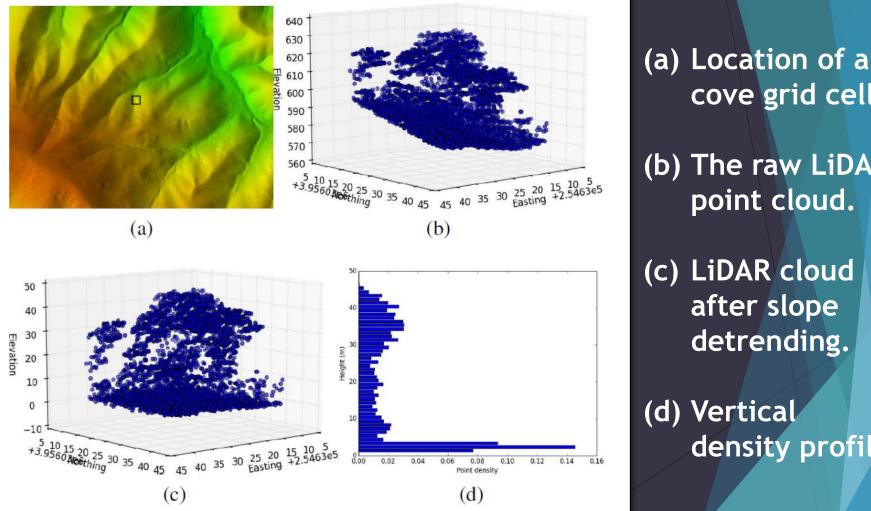

SAVANNAH

(5) Non-hierarchical K-means clustering reiteratively identified 10, 20, 40, 75 and 200 unique structural types

The processing was conducted using a supercomputer at Oak Ridge NL

<u>Subsequent landscape analysis</u> used a 250,000 random point sample of various rasters for jurisdictional, land use history, vegetation compositional and topographic gradient analysis.

LiDAR data preparation

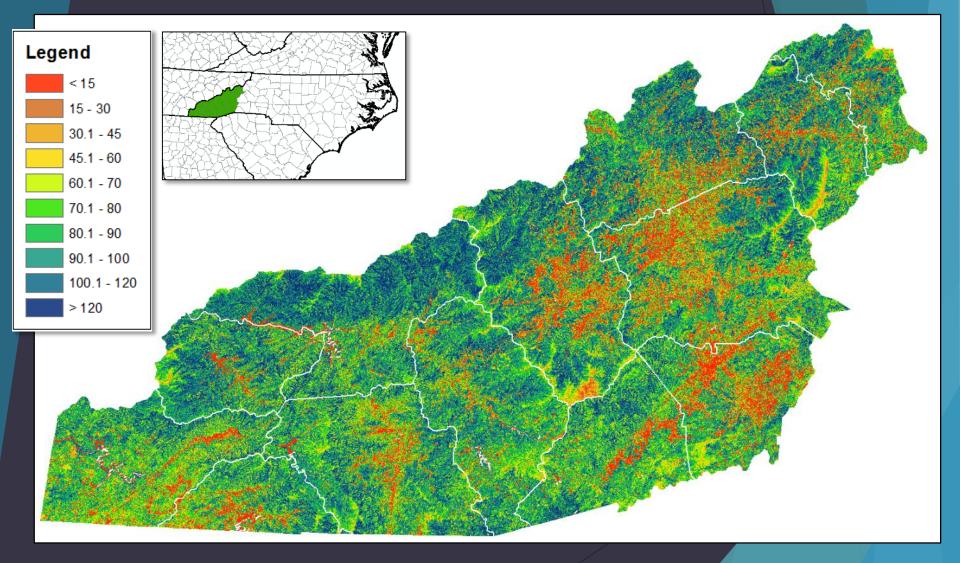

cove grid cell. (b) The raw LiDAR point cloud. (c) LiDAR cloud after slope

detrending.

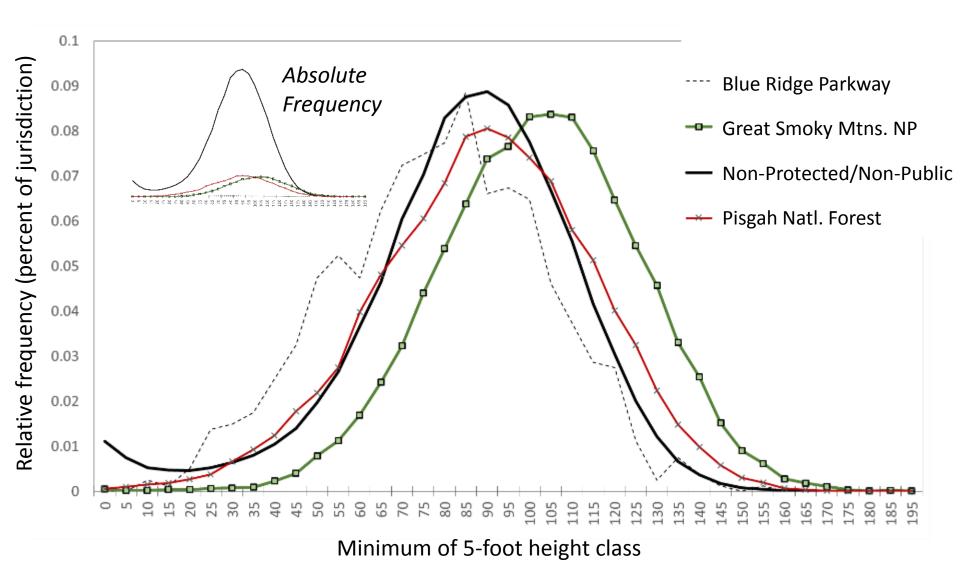

(d) Vertical density profile

Maximum vegetation height from LiDAR Across a 13-county area of western NC

Distributions of max. height by jurisdiction

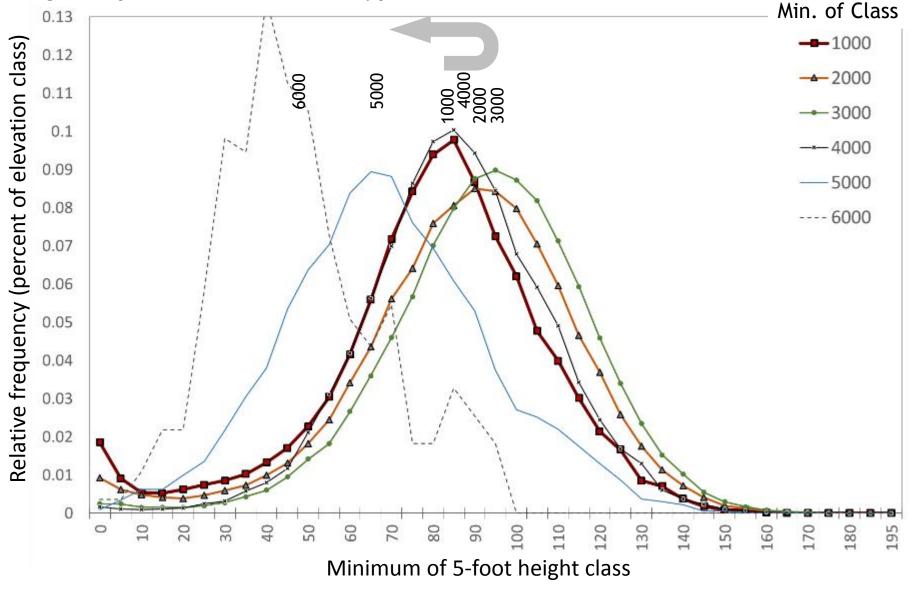

Regional pattern of "Natural" types

N= BRP: 802; GSMNP: 19,839; Non: 120,514; Pisgah NF: 21,991 (Sum: 163,146)

Distributions of max. height by elevation

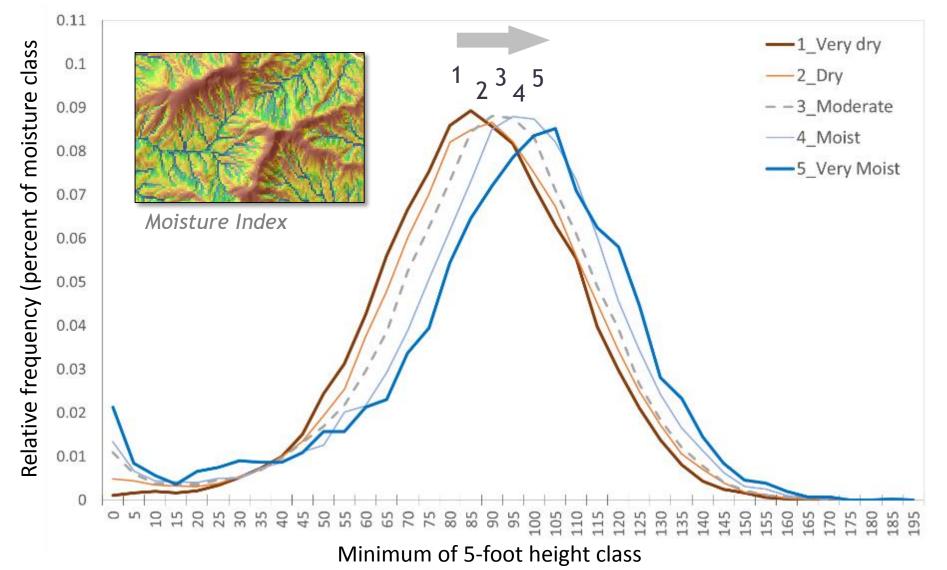

Regional pattern of "Natural" types

N=210,248 randomly sampled 20x20m LiDAR grid cells

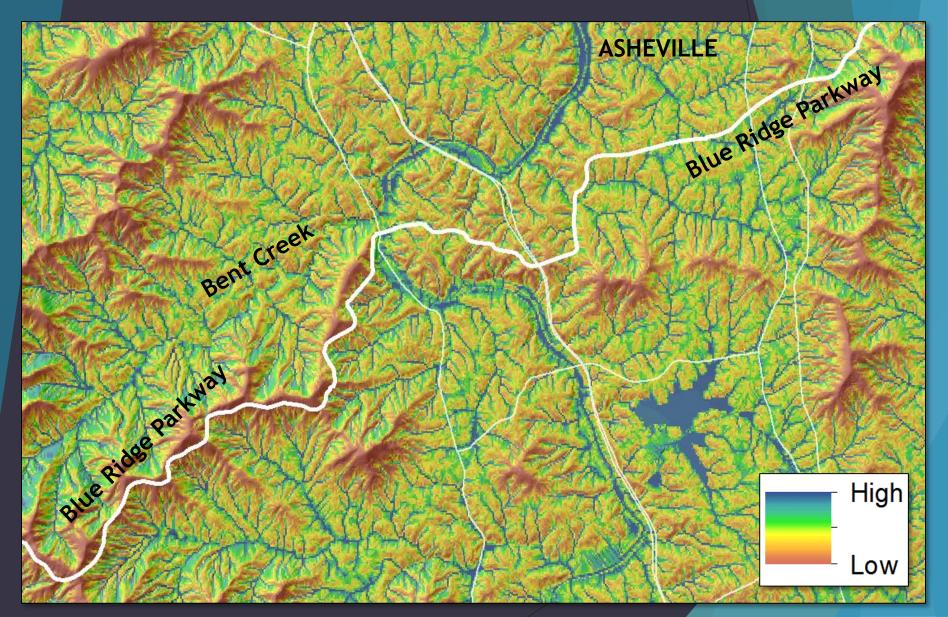

Distributions of max. height by moisture index

Regional pattern of "Natural" types

N=210,248 randomly sampled 20x20m LiDAR grid cells

The Parkway's preference for high and dry sites Topographic Moisture Index (TIMI)

The NC Blue Ridge Parkway's "topographic niches"

Summary

(1) Across North Carolina's Appalachians, vegetation height is predominantly explained by elevation and moisture gradients, with disturbance history of local significance.

(2) The NC Blue Ridge Parkway's forests are of lower stature than surrounding jurisdictions due to the Parkway's preference for higher and dry slopes. This "niche" may present different management challenges and opportunities.

(3) Casual inspection of the Parkway's edge effects using both max canopy and the full classification finds complex and ambiguous patterns. While hard roadside edges are common, the Parkway's natural structure is highly variable, and this nuances impacts along the Parkway's course.
