The Global Carbon Cycle: Implications for Life Beyond the 21st Century

Co-conveners: Forrest M. Hoffman (ORNL) and Abigail L. S. Swann (U. Washington)

3:30 pm The large, deep, slow contribution of soils to future climate–ecosystem feedbacks
Margaret S. Torn, Lawrence Berkeley National Laboratory

4:00 pm Ocean and land contributions to multi-century climates' carbon cycle feedbacks
James T. Randerson, University of California Irvine

4:30 pm Climate warming induces global reductions in marine biological productivity
Scott Doney, University of Virginia

We will wrap up at 5:00 pm and move the continuing discussion to

Tap House Grill
1506 6th Ave, Seattle, WA 98101

For optional no-host drinks and dinner.

In a fully coupled Earth system model run to year 2300, following the extended RCP 8.5 forcing (CO₂ mole fraction reached 1964 ppm), the 2 m air temperature over land increased by 11.6°C globally and approached 25°C at high latitudes.
